## Week 2

### Monday, June 10

Met with Rahul today to discuss possible directions where we could take the project, but my partner Fish was not present. Rahul summarized our meeting and sent a dense email filled with resources. I read through and took notes on "Dissipation of stop-and-go waves via control of autonomous vehicles: Field experiments" and on "The CAT Vehicle Testbed: A Simulator with hardware in the Loop for Autonomous Vehicle Applications." Tomorrow I hope to read the rest of the papers (4) in the email that concern the FollowerStopper. On Wednesday and Thursday I hope to familiarize myself with ROS, Gazebo, and the Testbed. Over the weekend I hope to focus on learning Simulink and supplementing my knowledge of control systems.

### Tuesday, June 11

I read through and took notes on "Dissipation of emergent traffic waves in stop-and-go traffic using a supervisory controller," "Tracking vehicle trajectories and fuel rates in phantom traffic jams: Methodology and data," and "Real-time distance estimation and filtering of vehicle headways for smoothing of traffic waves." The first and third gave in-depth descriptions of the Follower Stopper controller. After reading, it is clear that the parameter in the FollowerStopper configurable quadratic bands can be optimized through more research. The second paper discussed the circular phantom jam experiment, giving a special look on the tracking methods employed to find the instantaneous positions, velocities, accelerations, and fuel rates of all vehicles in the experiment. The third paper focused on the designing of filters to reduce the noise in relative velocity data of the lead vehicles and to calculate the expected separation distance between the AV and the lead vehicle. I came up with a few questions because of the reading: Would it be beneficial to research how animals respond to "traffic" in a herd? What if we looked at how acceleration/deceleration cause car-sickness or imbalance in the ear when determining the maximum deceleration parameter in the FollowerStopper? Would it be possible to develop a closed-form mathematical model establishing a relationship between safety metrics, sensor frequency, and desired accuracy of the sensors in order to optimize use of more inexpensive sensors?

### Wednesday, June 12

I spent most of the day trying to unsuccessfully download MATLAB on my laptop. Otherwise, I have been working through ROS tutorials. I made it through about half of the tutorials on <http://wiki.ros.org/ROS/Tutorials>, and I hope to make it through the rest by tomorrow.

### Thursday, June 13

I tried to work with Simulink, but my computer took exceptionally long and would keep freezing in Gazebo. Additionally, I spent some time trying to understand ROS.

### Friday, June 14

After spending the day gaining information from students, administrators, and professors about graduate school, I tried to improve upon my understanding of ROS. I worked through the rest of the ROS tutorials that I had started on Wednesday, and I watched some YouTube videos to see alternative projects and demonstrations of use. Though I still struggle conceptually understanding

ROS, I will suspend further work on the program until I have a task to complete, as then I will be able to have a more intentional goal when using the program.

### **Saturday, June 15**

Read through chapters 4-7 of *Vehicle Dynamics and Control* by Rajesh Rajamani. "Chapter 4: Longitudinal Vehicle Dynamics" considered the forces acting on the vehicle in the powertrain. Vehicle dynamic equations were strongly influenced by longitudinal tire forces, aerodynamic drag forces, rolling resistance forces, and gravitational forces. The powertrain consisted of an internal combustion engine, torque converter, transmission, and wheels. "Chapter 5: Introduction to Longitudinal Control" provided an introduction to several longitudinal control systems, including standard cruise control, adaptive cruise control, collision avoidance, control of vehicles in platoons, and anti-lock brake systems. Longitudinal control refers to the controlling of the longitudinal motion of the vehicle (e.g. velocity, acceleration, distance from preceding vehicle) through actuation of the throttle and the brakes. In cruise control, there is an upper level controller that determines the desired acceleration and a lower level controller that determines the throttle input required to track the desired acceleration. "Chapter 6: Adaptive Cruise Control" explained that the ACC system is an extension of the standard cruise control, equipped with a radar or other sensors that measures the distance to other preceding vehicles on the highway. ACC systems are autonomous, meaning that only on-board sensors are used and there is no communication between vehicles. There are two modes of steady-state operation: 1) speed control and 2) vehicle following (i.e. spacing control). Additionally, the vehicle following control system must satisfy individual vehicle stability and string stability. To define each form of stability, it is necessary to know that spacing error refers to the difference between the actual spacing from the preceding vehicle and the desired inter-vehicle spacing. The ACC control law is said to provide individual vehicle stability if spacing error converges to zero when the preceding vehicle is operating at a constant speed. The string stability of a string of ACC vehicles refers to a property in which spacing errors, during acceleration and deceleration, are guaranteed not to amplify as they propagate towards the tail of the string. Even by this definition and several other definitions, I am still confused by the notion of string stability. Why would string stability matter if in steady state the spacing error is zero? The chapter also proves that the constant time-gap spacing policy rather than the constant spacing should be used to achieve individual vehicle stability and string stability. "Chapter 7: Control for Vehicle Platoons" determines that the vehicle following control system in a platoon should also satisfy individual vehicle stability and string stability. The chapter determines that string stability can only be insured with the constant spacing policy if intervehicle communication is used.

### **Sunday, June 16**

I had not yet reviewed my notes or finished my daily journaling, so I created this LaTeX document and reviewed how to use GitHub, as I have never used it before. Because I still have trouble understanding string stability but did not have enough time to read all of the papers emailed to me by Rahul in depth, I skimmed all of them. I might give a detailed account of each one in future days. I am still trying to figure out the best way to read the papers. Over the past week, it would take me on average 3 hours to read a paper because I would take such intense notes in order to help me to stay focused on the material, clarify what was new information, and to provide a source to review if I want to get a general overview of a paper from my own perspective. I hope to discuss

with Rahul tomorrow if such time spent is worthwhile or wasted, as I could try to read one paper every hour so that by the end of a week I could have forty papers read. In the past I have preferred to print out papers in order to mark them up, but the inavailability of a printer and large quantity of pages I would be printing makes this option unreasonable. The benefit of my current note-taking is that it forces me to read the paper very closely, but again, I do not know if this is a waste of time. Should I be reading papers to search for something, to accomplish a goal, or to gain information for the purpose of improving my knowledge of the subject? I think it would be beneficial for Sunday to be a day of review for me, where I look back over every paper I have read during the week and do not look at any new material. This would prepare me for the weekly meeting and give me direction for future work. My foremost goal at the meeting tomorrow is to gain an understanding of how many papers I should be reading, to what depth, and by means of what notation. I hope to give more thought into my daily journals, giving true summaries of the works I read, indications of the things I accomplished, and bibliographies for all of the sources I use.

## **Week 3**
